3 January 2020

Abstract

Does local oversight improve public service delivery? We study the effect of a mobile phone application that allows citizens to monitor school construction projects in Brazilian municipalities. The app prompts users to submit data about construction sites, sends such crowdsourced information to independent engineers, and contacts the mayors’ offices about project delays. Our results show that the app has a null impact on school construction indicators. Additionally, we find that politicians are unresponsive to individual requests. The results question the impact of bottom-up monitoring on public service performance and suggest that interventions targeted at other groups, or focused on different issues, may produce better policy outcomes.

A Balance Tests

The tables below show the results of the balance tests we conducted for interventions 1 and 2. Our covariates are:

1. Log of municipal population in 2015;
2. Log of number of poor families in each city;
3. Log of total federal transfers to the municipality in 2016;
4. Federal government indicator for primary school quality;
5. Federal government indicator for secondary school quality.

The data come from the Brazilian Ministry of Education and the National Census.

In intervention 1, we randomised the treatment at the municipality level. We selected 150 municipalities for the control group while the rest were placed in the treatment group. We created the control group by deleting all the construction sites in the selected cities. No difference between control and treatment variables is statistically significant.

## IDEB Final Years (2015)	4.01 (0.84)	3.99 (0.80)	0.746
##			

In intervention 2, we randomised the treatment at the school level. We placed 15% of schools that could potentially appear in the app in the control group. We used block randomisation, blocking by three characteristics:

1. Brazilian State
2. Construction Status (under construction, stopped, unfinished)
3. School construction completion rates above the national median

B Manipulation Checks

In randomised experiments, manipulation is defined as the extent through which the treatment is successfully delivered to the control and treated units. In the case of the *Tá de Pé* app intervention, the manipulation indicates whether the app improves school construction completion rates. We present two manipulation indicators. First, we look into municipalities which did or did not download the app. Next, we see the number of app downloads during intervention 1 (February 2017–July 2018) and intervention 2 (August 2018–July 2019). The code replicates figures 2 and 3 in the article.

```
# Map manipulation test -- Intervention 1
mapbr <- get_brmmap("City")
gaaux <- filter(ga, phase1 == 1)
gaaux <- select(gaaux, ibge_code7, downl)
gaaux <- rename(gaaux, City = ibge_code7)
gaaux <- unique(gaaux)
gaaux$City <- as.numeric(gaaux$City)
gaaux2 <- impact_evaluation_phase1 %>%
  select(ibge_code7) %>%
  transmute(City = as.numeric(ibge_code7)) %>%
  unique()
gaaux <- merge(gaaux2, gaaux, all.x = TRUE); rm(gaaux2)

C Treatment Definition and Mechanism

In this section, we explain in detail how the *Tá de Pé* app works. The treatment involves the following procedures:

1. Users download the app.
2. Users access the app and add new information about school constructions near to their location.
3. The app sends a message to the mayor's office requesting details about the project. If necessary, the message is also forwarded to other government oversight institutions such as the city council and the Brazilian Federal Comptroller (CGU). Below, we discuss the cases in which we forwarded the denounce to the authorities.
4. If the pressure over the mayors has an effect, we expect to witness improvements on governmental data regarding the school construction progress.

The treatment is a compounded treatment comprised of steps (2) to (4). To make sure that the only source of the effect comes from step (2), we took the following precautions:

In step (1), we have implemented Facebook campaigns in municipalities that have school construction agreements with the Federal government. We did not discriminate any municipality in

this step, and citizens living in municipalities in the treatment and in the control could equally have received the banners about the *Tá de Pé* app. The Facebook campaign was not randomised.

For step (3), we put a team of two data scientists to ensure that upon receiving a denounce, the mayor's office, the city council, and the Brazilian Federal Comptroller (CGU) would be notified. The decision making funnel was:

3.1. We notified the *Engineers without Borders* (EWB) about the denounce and sent them the user-provided pictures and auxiliary information. They issued a report on how much the construction was likely to be delayed.

3.2. After we had the EWB report, we notified the mayor's office in compliance with Brazil's Freedom of Information Act (FOI). We communicated that a citizen had anonymously made a denounce about a school (fully identifying the school construction that we were referring to), and that the Engineers without Borders found the construction delayed. We submitted a request for the mayor's office to provide an explanation on why the construction was delayed and asked for updated statistics on when the construction will be finished. According to the FOI law, the mayor had twenty days to respond.

3.3. If the response was deemed insufficient, we forwarded the denounce to the city council and to the Brazilian Federal Comptroller (CGU). As the denounce goes to these institutions, they can harm mayors by restricting access to Federal funds.

3.4. At each stage, a Twitter bot constructed by *Transparência Brasil* (<https://twitter.com/tadepeapp>) reported the reception of a denounce and tracked the responses of the mayor, the city council, and the CGU.

In step (4), we relied on administrative data by the Brazilian Ministry of Education. The Ministry of Education provides monthly data on school constructions build with Federal Government resources and shows how many of them are delayed across the country. We use the finishing dates reported by the municipality at the time they sign the agreement with the Federal Government as our measure of construction delays. This data helped us to keep the app updated. We selected outcomes six months before and after the treatment. The data were constantly updated by the Ministry of Education, and we found no red flags in the overall quality of their information.

Therefore, steps (1), (3), and (4) were standardised and do not vary across the country. The only source of variation in our intervention should come from step (2).

In step (2), we applied the treatment by removing schools within municipalities out of the app. In the first intervention, which happened at the municipal level, we excluded all schools within a given randomly selected municipality. In the second intervention, we randomly excluded selected schools out of the app. Removing a school means that the school was in the dataset provided by the Brazilian Ministry of Education, but it did not show up in the app. Therefore, our treatment effect represents the school being present (treatment) or absent (control) in the app.

We argue that the app promotes two crucial features of bottom-up accountability. First, it helps people to access information that would otherwise be available only in an obscure spreadsheet on the Ministry of Education website. Second, whenever people find this information troublesome, we are providing an easy way for them to act upon the information. As the *Tá de Pé* design was intuitive and straightforward, we believe that most Brazilians would find it easy to use the app.

Moreover, the success of treatment does not require that everyone in the municipality uses it. The more usage means more pictures and denounces, and this represents more pressure over the mayors' office, which could revert into a higher effect. However, just one denounce would be enough for the project to be successful, as the denounce can be directed to the Brazilian General Comptroller (CGU), and this could potentially deny future funding to the municipality.

D Outcome Data Collection

We collect the main outcomes using the data reported by the municipality to the Brazilian Ministry of Education. Note that this is the same data as the pre-treatment data that we use to feed in the app with delayed schools.

The outcomes used in the paper are:

1. Percentage of the project completed before the impact evaluation started: This is a column in the Ministry of Education dataset. The data in this column were sampled at the beginning of the intervention.
2. Percentage of the project reported as completed by the end of the intervention period: Another column in the Ministry of Education dataset. The data were sampled six months after the intervention.

3. Difference between the percentage reported as completed before and after the intervention: The difference between (1) and (2) above. Note that according to Gerber and Green (2012), this way to look into outcomes is positive, as having a pre-treatment covariate that highly predicts the outcome reduces the variance in the estimator considerably.
4. Dummy indicator for finished constructions: The Ministry of Education dataset has a column with the construction status. We created a dummy to be one when the construction was reported as finished and zero otherwise. The data here were sampled six months after the intervention.
5. Dummy indicator for cancelled constructions: Similarly, we created a dummy variable from the Ministry of Education dataset indicating when the construction was reported as cancelled. The data here were sampled six months after the intervention.
6. Number of schools where construction companies updated the conclusion dates: Lastly, the Ministry of Education dataset has a column with the construction estimated completion date. We took the completion dated reported before and six months after the intervention. If the dates differed, we coded as one, and zero otherwise.

All these variables come from our manipulation of the Ministry of Education data. Collecting the outcomes in this way is superior to the alternative of gathering the data ourselves. First, we would not be able to manipulate the results and cherry-pick favourable results. Even if they have the best intentions, researchers may bias the results just by the choices they make in the data collection process. For instance, if we send an RA to collect the data, as she knows the app, she could unconsciously over-report positive results. This would bias our findings and undermine the credibility of our experiment. Second, using external data makes the results easily reproducible by other researchers. As the Ministry of Education has standardised data collection procedures, they greatly simplify and facilitate the reproduction of our findings.

E Facebook Tá de Pé Campaign

The app by itself would probably not have had an effect on the responsiveness of mayors. To boost usage and publicize the app, Transparência Brasil ran 64 Facebook campaigns throughout the country.

The Facebook campaign concentrates the bulk of the investments at the beginning of the intervention. The app download data is in the second panel of Figures 2 and 3. For the Facebook interaction, we have the following statistics:

1. Impressions

- Total for all campaigns: 5,155,535

2. App Download link clicks:

- Mean: 24,398.65

- Total for all campaigns: 1,951,892

As we see from the actual download activity, the people who indeed downloaded the app were much fewer than these numbers would suggest.

We have chosen Facebook because the platform offers an easy and cheap method to spread information. Moreover, according to the Statista website, Facebook is used by 70 million Brazilians (60% of the entire adult population), and the demographics largely match the demographics publicised by the Brazilian Institute of Geography and Statistics. For instance, see the following websites:

1. [Statista Total Facebook Users](#)

2. [Statista Total Facebook Users by Age](#)

F Main Results

G Randomisation Inference

We employ randomised inference to estimate the probability of the sharp null hypothesis over all possible randomisations that could have occurred under our research design. We fail to reject the null in all but the finished school indicator in experiment 1.

Figure 3: Sampling distribution of the estimated coefficient for our six outcomes in two interventions. Graphs on the left correspond to randomisation inference estimates for intervention 1 and those on the right describe the results for intervention 2.

H APSA Experimental Section Standard Report for Experimental Research

I Hypotheses

Hypotheses: The experiment studies how technology facilitates bottom-up and top-down pressure to improve service provision. More precisely, we test whether the *Tá de Pé* mobile phone app is able to successfully mobilise citizens to exert pressure on local representatives and civil servants. We also test whether bottom-up monitoring of public works improves school construction rates and spending.

****Background**:** Recent studies show that community monitoring improves public service outcomes in developing economies. Some of the papers find that bottom-up accountability has a significant impact on public service delivery:

- Bjorkman, Martina and Jakob Svensson. 2009. "Power to the People: Evidence from a Randomized Field Experiment of a Community-Based Monitoring Project in Uganda." *Quarterly Journal of Economics* 124(2):735-769.
- Bjorkman, Martina and Jakob Svensson. 2010. "When Is Community-Based Monitoring Effective? Evidence from a Randomized Experiment in Primary Health in Uganda." *Journal of the European Economic Association* 8(2-3):571-581.
- Bjorkman Nyqvist, Martina, Damien de Walque and Jakob Svensson. 2017. "Experimental Evidence on the Long-Run Impact of Community-Based Monitoring." *American Economic Journal: Applied Economics* 9(1):33-69.

However, other authors fail to find positive results for the same type of intervention, e.g.:

- Banerjee, A. V., Banerji, R., Duflo, E., Glennerster, R., and Khemani, S. 2010. "Pitfalls of Participatory Programs: Evidence from a Randomized Evaluation in Education in India." *American Economic Journal: Economic Policy*, 2(1):1-30.
- Lieberman, E. S., Posner, D. N., and Tsai, L. L. 2014. "Does Information Lead to More Active Citizenship? Evidence from an Education Intervention in Rural Kenya." *World Development*, 60:69-83.

- Raffer, Pia, Dan Posner, and Doug Parkerson. 2019. “The Weakness of Bottom-up Accountability: Experimental Evidence from the Ugandan Health Sector.” URL: <https://bit.ly/2L36vzI>

This project re-evaluates this theoretical controversy and proposes a new field experiment to test whether bottom-up accountability is effective to promote better policy outcomes. The results are substantively important as well. First, we conduct this experiment in a middle-income country, Brazil, which has municipalities whose social indicators match both those of developed and developing nations. Brazil is notably unequal in several characteristics, thus allowing us to infer results for different subgroups if required. Second, we are evaluating school constructions, and the presence of schools have essential consequences in terms of long-run economic development, the household income composition, and women empowerment.

II Subjects and Context

Eligibility and Exclusion Criteria: We selected all school projects that received Federal fundings from the Brazilian Ministry of Education. By an agreement with the Brazilian Ministry of Education, they allowed us to have the data of all school constructions receiving funds from them.

All schools constructions funded by the Brazilian Ministry of Education participated in this study. We had no schools excluded from the program.

Interventions’ dates: We ran two interventions:

- App impact evaluation 1: From August 2017 to February 2018. We call this Intervention 1 throughout the text.
- App impact evaluation 2: From August 2018 to February 2019. We call this Intervention 2 throughout the text.

III Allocation Methods

Assignment Procedure: The treatment here was assigned by the municipality in the first intervention, and at the school level in the second and third interventions.

For intervention one, we selected 150 municipalities that were placed in the control group. The randomization code was:

```

vectreat <- c(rep(0,150), rep(1, nrow(dat)-150))

AIC_info = numeric()
for (i in 1:5000) {
  vectreat <- sample(vectreat, length(vectreat))
  mod <- glm(formula(paste('vectreat', vars, sep = '~')),
             family = binomial, data = dat)
  if(sum(summary(mod)$coefficients[-1,4]<.2)==0) {
    dat = data.frame(dat, vtreat = vectreat)
    AIC_info = c(AIC_info, AIC(mod))
  }
}

```

Then, we checked whether the one of the selected covariates is a significant predictor of the random assignment. We presented a vector of acceptable random assignment in these grounds, and Transparência Brasil selected the one we use in the first intervention.

For intervention 2, we selected 15% of the schools in the dataset that could either be placed in the treatment or in control in each of the interventions. The randomizr code for intervention 2 follows below. OnApp means treatment and OffApp means the control for this intervention:

```

# Install and load required package
install.packages("randomizr")
library(randomizr)
decl_intheapp <- declare_ra(blocks = dat_intheapp$var_blocking,
                           prob_each = c(.85,.15),
                           conditions = c('OnApp', 'OffApp'))

dat_intheapp$Z_intheapp <- block_ra(blocks = dat_intheapp$var_blocking,
                                   conditions = c('OnApp', 'OffApp'),
                                   prob_each = c(.85,.15))

```

```
dat_intheapp$IPW_intheapp <- 1/obtain_condition_probabilities(decl_intheapp,
                                                         dat_intheapp$Z_intheapp)
```

Block randomization: We used simple randomisation in the first assignment. In the second intervention, we blocked by the Brazilian State, the construction status, and above the median execution. The summary of the blocks, with the IPWs assigned follow below.

```
aux <- rand2018 %>%
  select(state, status, above_median_executed,
         var_blocking, Z_campaign, IPW_campaign) %>%
  unique() %>%
  na.omit()
kable(aux, "latex", caption = "Block randomization -- Intervention 2",
      booktabs = TRUE, longtable = TRUE) %>%
kable_styling(font_size = 8) %>%
kable_styling(latex_options = c("hold_position", "repeat_header"))
```

As pre-treatment variables, we used the following municipality-level characteristics:

1. Log of Municipal Population in 2015
2. Log of Number of Poor Families (2010 IBGE Census)
3. Log of Total Federal Transfers to the Municipality in 2016
4. IDEB Indicator for Primary School Quality (2015 Ministry of Education)
5. IDEB Indicator for Secondary School Quality (2015 Ministry of Education)

None of the pre-treatment variables were significant, as shown in Section A.

IV Treatments

- **Treatment Groups:**

- *Intervention 1:* Municipality with all schools funded by the Ministry of Education showing up in the app.
- *Intervention 2:* School construction showing up in the app.

- **Control Groups:**

- *Intervention 1:* Municipality with all schools funded by the Ministry of Education **not** showing up in the app.
- *Intervention 2:* Selected school constructions **not** showing up in the app.

- **Method of Manipulation Delivery:**

- *Intervention 1*: The municipalities in the treatment had all their school constructions showing up in the app.
 - *Intervention 2*: The schools in the treatment group were showing up in the app.
- **Software**: The TDP app is an Android and iOS application developed to facilitate bottom-up pressure on school constructions in Brazil.

V Results

- **Outcome measures**: We use six outcome measures, all taken from the Ministry of Education biannual report:
 1. Percentage of the investment executed before the impact evaluation started (placebo)
 2. Percentage of the investment executed by the end of the impact evaluation period
 3. The difference of the percentage invested in the end and in the beginning of the impact evaluation period
 4. Indicator for a construction finished during the impact evaluation period
 5. Indicator for a construction cancelled during the impact evaluation period
 6. Indicator for an updated conclusion date for the construction during the impact evaluation period

- **CONSORT**

Below follows the CONSORT chart flow:

- *Intervention 1*:

• *Intervention 2:*

• **Reasons for exclusion in the CONSORT:**

- *Intervention 1:* Constructions that were not in the app when the intervention started.
- *Intervention 2:* Constructions that were not in the app when the intervention started.

- **Statistical analysis:**

For all interventions, we run the following regression model:

$$Y_i = \alpha + \beta T_i + \gamma X_i + \theta F_i + \varepsilon_i$$

Where i indexes a given school observed in the intervention. Y_i represents an outcome variable. T_i represents a treatment indicator. β represents the estimated Average Treatment Effect. γ is a vector of pre-treatment coefficient effects and X_i a vector of pre-treatment covariates. θ represents a vector of fixed effects estimands and F_i the Brazilian state level fixed effects indicator vector. ε_i is the common error term.

We run three types of analysis:

1. Full regressions with all data available
2. Full regressions using inverse probability weights
3. Regression where we match the control group with a same-size treatment group on the proximity of covariates using genetic matching.

All models use municipal-level cluster robust standard errors and state-level fixed effects. For all models, we also run regressions without clusters or fixed effects.

I Other Information

- **IRB:** FGV exempted the investigators from getting IRB approval because this research used online data and was approved by the Brazilian Ministry of Education.
- **Pre-Registration:** this research has been pre-registered on the EGAP pre-registry tool: <https://egap.org/registration/4505>.
- **Replication Materials:** The replication materials for this project are available here: <https://github.com/umbertomig/tdp-accountability>.
- **Funding:** This research received funding from the 2016 Google Social Impact Challenge. Google did not interfere in any aspect of the research design and analysis.
- **Conflict of Interests:** The authors of this analysis declare that there are no conflict of interest.

J Session Information

We used R version 3.6.2 (2019-12-12) to write the manuscript and this appendix. For the regression models estimation, we used the `lfe` package. We employed the `MatchIt` package to improve covariate matching. Everything in this report is fully automated and can be reproduced using RMarkdown.

`sessionInfo()`
